DYSTONIA CAUSED BY USE OF PROCHLORPERAZINE IN HYPEREMESIS GRAVIDARUM

E Obudu, MBBS; D Burch, MRCOG

INTRODUCTION

Nausea and vomiting are common symptoms in early pregnancy, but true hyperemesis gravidarum (HG) is rare. We present a multigravid patient with hyperemesis who showed mental status changes in the 12th week of pregnancy as a consequence of antiemetic therapy.

CASE REPORT

A 29-year-old lady presented to the gynaecology emergency unit with a ten-day history of worsening nausea and vomiting with reduced urine output despite taking oral antiemetics. Pregnancy test was positive. She had suffered similar symptoms in her first pregnancy. Her weight at booking was 51kg.

Clinical examination showed her to be severely dehydrated with heavy (3+) ketonuria, pulse rate 73/min, BP 110/70 mmHg. Systemic examination was normal. Blood results showed normal haematological, biochemical and thyroid indices. Pelvic ultrasound scan confirmed a single intrauterine pregnancy at eight weeks’ gestation. She was managed with intravenous fluids and parenteral antiemetics (prochlorperazine and metoclopramide) and discharged two days later.

Following several admissions over the subsequent weeks (latest at 12 weeks gestation), she had become quite frail looking with 16% weight loss (43kg). Blood results showed hypokalaemia which was corrected. Parenteral vitamin B1 in order to prevent the development of Wernicke-Korsakoff syndrome (WKS), thiamine deficiency) and thrombophrophylaxis was started. Naso-gastric tube feeding was commenced following a dietician review. She tolerated this for only 24 hours. She was only on prochlorperazine at this point.

In the four days following admission she gradually developed oro-facial dystonia, retracted upper lips, slow tongue movements, dysarthria, dysphasia and dysphagia. There was no facial weakness or postural disturbance. Cranial nerve, optic fundi, reflexes and power were all normal. There was no past history of neurological illness.

A neurologist diagnosed drug-induced dystonia secondary to prochlorperazine. This was discontinued and she was started on oral procyclidine, 5mg thrice daily. She showed dramatic improvement within two hours and was discharged home the following day. Review in the antenatal clinic two weeks later showed her to be in good health with complete resolution of symptoms. Her anomaly scan at 20 weeks was normal and the subsequent antenatal course was managed as low risk.

DISCUSSION

Nausea and vomiting during pregnancy is a common experience affecting 50% to 90% of all women. HG is the most severe form of nausea and vomiting occurring in pregnancy. Between 0.3% and 2% of all pregnant women suffer from the condition.

It is characterised by intractable nausea and vomiting leading to dehydration and ketonuria, electrolyte and metabolic disturbances, and nutritional deficiency with associated weight loss (≥5% body weight) that may require hospitalisation. The onset of symptoms is usually in the first trimester of pregnancy but the socioeconomic impact on time lost from paid employment or household work can be immense.

The cause of HG is poorly understood but it is essential to exclude other causes of similar symptoms (see table 1).

Table 1 Differential diagnosis of hyperemesis gravidarum

Associated neurological signs in HG (WKS, or drug-induced following use of antiemetics leading to dystonic reactions, or oculogyric crisis in severe cases) may be secondary to thiamine (vitamin B1) deficiency. Hyponatraemia and its rapid reversal may cause fatal pontine myelosinosis.

WKS is a rare but known complication of severe HG caused by thiamine deficiency. There are only 49 published cases in the literature to date. The classic triad of symptoms – confusion, oculair signs and ataxia – were manifest in only 47% of patients (23 of 49). Other signs include nystagmus, headache, vertigo, altered consciousness, memory impairment. Of the 49 cases, the mean age was 27 years and the mean gestational age was 14 weeks. The overall pregnancy loss rate, directly (spontaneous fetal loss) and

incredibly restless
agitation
fixed eye stare
backward and lateral flexion of the neck
widely opened mouth
tongue protrusion
ocular pain

Table 2 Features of oculargyic crisis

OGC is a severe dystonic reaction to certain drugs or medical conditions. Features can be recurrent if there is continued exposure to the precipitating factor and may include those features and factors shown in tables 2 and 3.

Immediate treatment of drug-induced OGC can be achieved with intravenous benztpine or procyclidine, which are usually effective within five minutes, although may take as long as 30 minutes for full effect. Any causitive new medication should be discontinued. The abrupt termination of the psychiatric symptoms at the conclusion of the crisis is most striking.

GEORGE CUP RESULT 2008
This year's George Cup Golf Competition was held on Saturday, 7th June, at Morecambe Golf Club. There was an excellent turnout with 24 golfers playing.

The competition results are as follows:

The George Cup
Ms Christine Brander 43 points
Mr Sanj Prashar 34 points
Dr Malcolm Brown 33 points

The John Wilkie Quaiche
Ms Christine Brander 22 points

The Phil Allen Plate
Mrs Lisa Higham 44 points

The Freend's Silla
Mr David Lavelle 33 points

An excellent day in glorious weather. Hopefully, next year's competition will be held at Heysham Golf Club.

Andrew Whitton, Golf Secretary
